1. INTRODUCTION

This preliminary drainage report has been prepared in support of a Vesting Tentative Map Entitlement submittal for the Trails at Carmel Mountain Ranch Project (the Project), which is located in the City of San Diego, California. The purpose of this report is to determine the hydrologic impact, if any, to the existing storm drain facilities or natural drainage, and to provide peak 100-year discharge values for the project.

The drainage analysis presented herein reflects a Vesting Tentative Map level-of-effort, which includes peak 100-year storm event hydrologic analyses using preliminary grades. Hydraulic analyses for inlets, pipe sizes, inverts, and HGL's will be provided during final engineering. Therefore, the purpose of this report submittal is to acquire from the City of San Diego: 1) concept approval of the proposed storm drain layout, 2) approval of the methodology used in the evaluation of the project storm drain system hydrology, and 3) identification of critical path drainage issues that need to be addressed during final engineering.

The Trails at Carmel Mountain Ranch Project is a proposed residential community located in the City of San Diego. The site is approximately 164.5 acres in size and is located east of Interstate 15, west of Pomerado Road, and between Carmel Mountain Road and Ted Williams Parkway. The Property was formerly operated as a golf course and is currently owned by PACS Enterprises, LLC. The Proposed Project includes approximately 101.2 acres of open space (including natural open space, landscaped slopes, and parkland), and a total of approximately 1200 residential units. The vicinity map is shown in Figure 1.

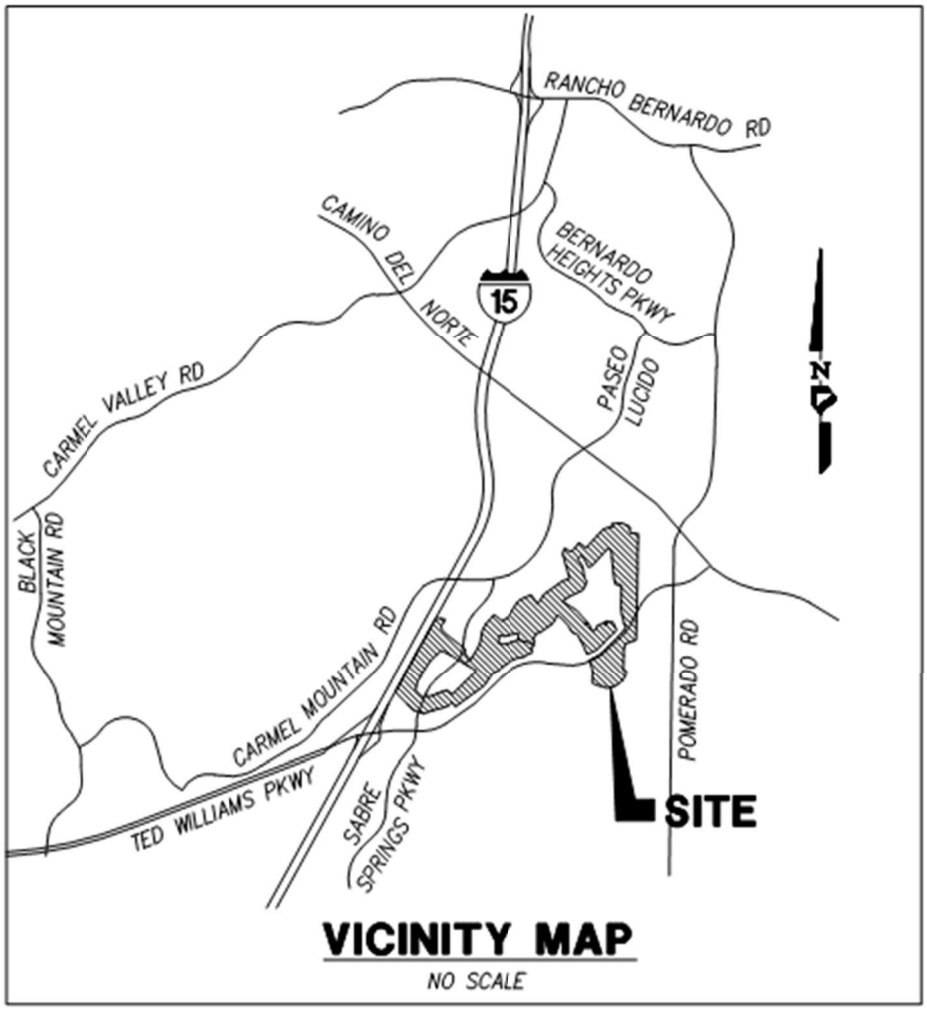

Figure 1: Project Vicinity Map

Redevelopment of the site will involve demolition of the existing golf course and regrading of the site to a usable condition compatible with future land uses. The project will not require a 401 Certification or an Army Corps of Engineers 404 permit. A blend of market rate homes, multi-family homes, and affordable housing is to be constructed including all associated landscaping, hardscaping, and utilities.

From a regional drainage perspective, the project's storm drain system will discharge into Los Penasquitos Creek. There is one FEMA special flood hazard area near the project site, see Appendix 1 for the full FEMA Firm.

Treatment of onsite storm water prior to discharging into the downstream systems will be facilitated by several biofiltration basins. For a detailed discussion of the project's stormwater quality BMPs and hydromodification management approach, refer to the Preliminary Stormwater Quality Management Plan (SWQMP) report. For the Southern California Coastal Water Research Project (SCCWRP) channel screening report for the project, refer to the SCCWRP report prepared by Chang Consultants and submitted under a separate cover. The SCCWRP report documents the channel erosivity analysis, which was used to document the low flow threshold to be used for design of the proposed hydromodification management facilities. The final post-construction BMP design will be provided during final engineering.

2. EXISTING AND PROPOSED DRAINAGE PATTERNS

2.1 Existing Drainage Patterns

The existing site is currently the location of the Carmel Mountain Ranch Golf Course and clubhouse. Generally the site drains to two different locations; the western half of the site drains west and is conveyed to outfalls in Chicarita Creek, and the eastern half of the site drains east and is conveyed to an outfall near Ted Williams Parkway on existing golf course hole 14. This water is then conveyed through natural canyons near Poway Fire Station 3 until it drains into Los Penasquitos Creek. Los Penasquitos Creek runs from east to west, and the runoff from Chicarita Creek eventually commingles with Los Penasquitos Creek at Cypress Canyon.

Because the majority of the area surrounding the project site is already developed, there is minimal run-on into the project site.

There are several existing private storm drain systems within the project site and two major public systems in the adjacent streets: a 72-inch CIP concrete storm drain per Drawing 22088-12-D on Shoal Creek Drive and a 72-inch RCP storm drain per Drawing 22745-23-D on Carmel Ridge Road. There are two additional storm drain system outlets near the project. A 48" RCP outlets into Chicarita Creek near Rancho Carmel Drive and a 54" RCP outlets into existing golf course hole 12 near Ted Williams Parkway.

Onsite, under existing conditions, the drainage from most holes generally sheetflows into a type F catch basin at the downhill side of the hole. A private storm drain attached to the type F CB then conveys water to one of the public storm drain systems listed above.

See Exhibit A in Appendix 6 for an existing conditions drainage map. Note that for some of the systems, the downstream limits of the onsite drainage areas were set to approximate the downstream limits of the proposed drainage areas, in order to compare similar areas in pre-project and post-project flows.

2.2 Proposed Drainage Patterns and Storm Drain Improvements

Redevelopment will disturb approximately 74 acres of the project site. Proposed development will not significantly alter ultimate discharge points of onsite and offsite runoff. There is minimal offsite runon onto the project site, and proposed onsite drainage patterns will mimic existing drainage patterns. Some local re-direction of runoff occurs onsite, however most flows converge in the storm drain systems that head to Chicarita Creek or Los Penasquitos Creek.

The west side of the project site (existing course holes 1, 2, 5, 6, 8, and 9) will continue to discharge to Chicarita Creek through either a 48" or 72" RCP. The east side of the site (existing holes 10, 11, 16, 17, and 18) will drain through a 72" RCP into natural canyons before converging with Los Penasquitos Creek. The proposed drainage improvements include private storm drains collecting rooftop and surface drainage and public storm drains in public roads that connect private pipes with the public storm drain system. Refer to Exhibit B in Appendix 6 for the proposed condition drainage map.

3. HYDROLOGY CRITERIA, METHODOLOGY, AND RESULTS

3.1 Hydrology Criteria

Table 1 summarizes the key hydrology assumptions and criteria used for the hydrologic modeling.

Table 1: Hydrology Criteria

Existing and Proposed Hydrology:	100-year storm frequency
Soil Type:	Hydrologic Soil Group D per Drainage Design Manual requirements
Runoff coefficients:	Based on land use in sub-drainage area, from C=0.45 to 0.95. See Rational Method output.
Rainfall intensity:	Based on the City of San Diego Intensity Frequency Duration Curves presented in the 2017 City of San Diego Drainage Design Manual.

3.2 Hydrology Methodology

Hydrology calculations were completed for existing and proposed conditions accounting for all areas draining to the onsite storm drain systems. Drainage areas were defined from existing and proposed topographic maps of the area. A hydrologic analysis was completed utilizing the Rational Method, outlined in the 2017 City of San Diego Drainage Design Manual. The goal of the Rational Method analysis was to determine the peak 100-year flow rates for the storm drain pipes by developing a node link model of the contributing drainage area and applying the intensity-duration-frequency (IDF) curve to the areas. See Appendix 1 for the City of San Diego IDF curve.

The Civil-D computer program was used to obtain peak flow rates for the offsite and onsite drainage areas under existing and proposed conditions. The Civil-D Modified Rational Method Hydrology Program is a computer-aided design program where the user develops a node link model of the watershed. Developing independent node link models for each interior watershed and linking these sub-models together at confluence points creates the node link model. The intensity-duration-frequency relationships are applied to each of the drainage areas in the model to get the peak flow rates at each point of interest.

The project drainage areas were split into multiple systems representing different outfall areas of concern. Generally, each existing course hole is a separate system. For the proposed condition, Systems 1000 and 2000 represent existing course holes 1 and 2, respectively. System 1000 drains to BMP 1, which is conveyed offsite by an 18" RCP per Drawing 22838-5-D, while System 2000

drains to BMP 2, which is conveyed offsite by an 18" RCP per Drawing 22088-3-D. System 5000 represents the area on existing hole 5 to the east of Chicarita Creek and outside of the environmental buffer. This area drains to BMP 5 and is conveyed offsite via a 48" RCP per Drawing 22917-5-D. System 6000 represents existing hole 6 and some run-on area from existing hole 7. This system drains to BMP 6 and is conveyed offsite via a 36" RCP per Drawing 22917-5-D. Both Systems 5000 and 6000 are conveyed to the Chicarita Creek point of compliance "A" (POC A) via the 48" RCP. System 8000 consists of the area that is existing condition course hole 8 and some hillside run-on. This area drains to BMP 8 and is conveyed offsite by a 48" RCP via Drawing 22939-3-D. System 9000 consists of a portion of existing hole 9 and the existing clubhouse parking lot. This system drains to BMP 9. System 9500 consists of the detained flow from BMP 9 and hillside bypass area from the remaining portion of existing hole 9. Systems 1000, 2000, 8000, and 9000 are all conveyed to the Chicarita Creek POC B within a 72" RCP via Drawing 22088-3-D.

System 11000 consists of existing course holes 10 and 11. This area drains to BMP 11 and is conveyed offsite by an 18" RCP pipe per Drawing 24565-2-D. The detained flow from BMP 11 is conveyed to the open space area POC E on existing hole 12. System 16000 consists of the existing course hole 16. This area drains to BMP 16 and is conveyed offsite and to the open space area POC C by a 72" RCP via Drawing 22745-21-D. System 17000 consists of the existing hole 17 and drains to BMP 17. System 18 consists of existing course hole 18 and the existing course clubhouse. This area drains to BMP 18. System 18500 consists of the detained flow from BMPs 17 and 18, and hillside bypass area on existing hole 18. This system is conveyed offsite by an 18" RCP via Drawing 26514-11-D. It eventually heads to natural canyon POC D. Flow from the 72" RCP at POC C is also conveyed through open space area to POC D.

Four systems are being planned as potential public city parks, and are pending City approval before a site plan is created. Because of this, a Civil D model for existing and proposed conditions for each system has been created based on the preliminary park footprints and assuming a proposed runoff coefficient of 0.45. Because the parks do not yet have site plans, the imperviousness of each park is currently unknown. Therefore, it is assumed that the stormwater quality approach for each park will be deferred until site plans are developed. The parks are anticipated to be almost exclusively pervious, with very little impervious area. There, this submittal includes no BMPs or

subsequent BMP calculations for water quality and hydromodification for these systems. System 7000 consists of existing course hole 7. This area drains to Chicarita Creek via POC B. System 13000 consists of a small portion of existing course hole 13, and flows to POC F. Systems 15000 (existing course hole 15) and 17500 (a portion of existing course hole 17) both drain to POC C which outlets into natural canyons on the east side of the site. Basin and/or BMP design for these systems will accompany a future submittal once each system land use is determined. However, as with all systems, flows for proposed conditions will be less than or equal to existing condition flows.

For comparison purposes, existing condition drainage systems are named similarly to the post-project drainage systems. For example, System 800 for existing conditions corresponds to System 8000 for proposed conditions. City of San Diego Drainage Design Manual runoff coefficients, based on land use, were assigned for each drainage sub-basin within CivilD. Additionally, site plans are still in development and therefore proposed conditions "C" values are estimated based on proposed land uses.

3.3 Hydrology Results

The results of the Rational Method hydrology modeling are provided in Appendices 2 and 3 and the results are summarized in this section. Redevelopment of the project site increased the 100-year runoff from the site, but peak flows after detention are less than either backbone storm drain system capacity or existing condition peak flow at the project outfall, whichever condition governs.

For all outfalls, proposed condition unmitigated peak flows are greater than existing condition peak flows. The existing condition 100-year peak flow of Outfall A near the southwest corner of the site is 15.7 cfs, whereas the proposed condition 100-year peak flow is 23.6 cfs. For outfall B (which represents flow from Systems 1000, 2000, 8000, and 9500), the unmitigated 100-year post-project flow rates are increased from 57.7 cfs to 101.9 cfs. Outfall E that represents flow from System 11000 increases 100-year post-project flow rates from 21.7 cfs to 39.6 cfs. Finally, Outfalls C and D (which represents flow in Systems 16000 and 18500, respectively) increase 100-year post-project flow rates from 8.3 cfs to 18.0 cfs and from 19.8 cfs to 31.0 cfs, respectively. However, preliminary detention modeling was performed for a couple of representative basins, and peak flows after detention are significantly less than the existing flows and backbone flows. During

final engineering, calculations will be prepared for all basins to show the final detained flow rates out of the detention basins. The combination of basins will be sufficient to ensure the graded total peak 100-year flow rate for the proposed condition is less than the maximum allowable peak flow rate. Therefore, there will be no adverse impact from a peak flow perspective.

For the results of the analysis, see Exhibit A for the existing conditions hydrology map and Exhibit B for the proposed conditions hydrology map in Appendix 6. Refer to the appendices for the hydrology calculations. Table 2 summarizes the hydrology results and compares existing and proposed conditions.

Table 2: Summary of Hydrology Results

Notes:

1) Backbone flowrates are based on As-Built Drawings (see Appendix 4)

2) System 9500 represents the combined routing result of Systems 9000 and hillside bypass area

3) System 18500 represents the combined routing result of Systems 17000 and 18000

4) Q100 values are shown as "<x.x" to indicate detained flow rates. During final engineering, detention calculations will be prepared to show the final detained flow rates out of the the detention basins. The combination of basins will be sufficient to ensure the grand total Q100 for the proposed condition is less than the maximum allowable Q100. The preliminary

3.4 Detention Basins

There are 10 detention basins proposed for the project site for water quality treatment and hydromodification management. From the Rational Method results for each of the systems draining to a basin, the proposed condition peak inflow hydrographs were generated with Rick Engineering Rational Method Hydrograph Generator. This program develops a synthetic hydrograph per the 2003 County Hydrology Manual using the results of the Rational Method output.

The inflow hydrograph for each system was then entered into Haestad Method's PondPack software and the detention routing was performed with the design of the detention basin and the proposed outlet structure. The 100-year hydrograph was routed through the basin to demonstrate that the post-development peak flow rate will comply with the detention requirements and that the detention facility will not overtop during the 100-year peak event. The time of concentration coinciding with the basin outflow peak was established by adding the inflow hydrograph time of concentration plus the lag time of the detained flow within the basin. This combined time of concentration accounts for the time of concentration to get to the basin and the detention time within the basin. The riser for each basin was designed to ensure that riser size, rim elevation, and orifice placement will work in conjunction to properly mitigate the increased flow rate.

Preliminary detention modeling has been completed for representative basins Basin 9 and Basin 11. A complete set of detention models will be included during final engineering. The preliminary hydrograph routing calculations and detention models are included in Appendix 5. With detention, the proposed 100-year flow rates at the project outfalls are less than the existing 100-year flow rates. During the City's review process, it was requested that a table be included that shows the proposed volume of the basins along with the minimum necessary volume for the drainage area conveyed to the basin. Table 3 on the next page shows the results for all DMAs/Basins. The table shows that the minimum detention volume of each basin is less than the proposed volume of the basin for each DMA, showing that the detention area is sufficient to detain peak Q100 flows. This table shows TM level-of-effort for the preliminary engineering submittal, during final engineering full detention calculations and results will be included in the report.

Table 3: Required DMA Detention Volume versus Proposed Basin Volume

Trails at Carmel Mountain Ranch Detention Volume Comparison					
DMA	Basin	Proposed Basin Volume (CF)	Post-Project Detention Volume Estimate (CF)	Pre-Project Runoff Volume Estimate (CF)	Minimum Detention Volume Needed From Basin (CF)
1	1	1.108	1.615	0.956	0.659
2	2	1.111	1.527	0.968	0.559
5	5	0.660	0.527	0.293	0.234
6	6	0.662	1.278	0.810	0.468
8	8	1.082	1.971	1.215	0.756
9	9	0.966	1.453	0.788	0.665
11	11	2.927	2.868	1.676	1.192
16	16	0.654	1.183	0.641	0.542
17	17	0.816	1.162	0.630	0.532
18	18	0.565	0.975	0.529	0.447

3.5 Water Quality Calculations

The water quality calculations are included, under separate cover, in the Storm Water Quality Management Plan (SWQMP) prepared by PDC. The biofiltration basins will be combined hydromodification/biofiltration/detention basins.

3.6 Hydromodification Analysis

The biofiltration basins also address hydromodification requirements, since both biofiltration basins and hydromodification basins produce similar alterations to the flow regime for the smaller, more frequent storm events. Flow duration control is the most common form of hydromodification management. The majority of all onsite water will be treated with biofiltration/hydromodification basins, which will detain the smaller, more frequent events and therefore will mitigate the post-development onsite flows. Refer to the Hydromodification report prepared by PDC for detailed calculations.

4. CONCLUSION

This drainage report supports the VTM for the proposed Trails at Carmel Mountain Ranch development. This report was prepared to ensure that project development would not adversely affect existing drainage patterns. Hydrology calculations indicate that redevelopment will result in an overall increase in flows from the site, but the total flow rates after detention is less than or equal to existing flow. Small onsite re-direction of flows does not alter general drainage patterns

as onsite storm drain systems ultimately discharge to the same location downstream of the project. As such, the project redevelopment should not have an adverse effect on local or global drainage patterns. The drainage system will be designed appropriately to accommodate the peak-flow conditions for the site. Detention calculations and pipe hydraulic calculations will be included during final engineering.

APPENDIX 1

Supporting Documentation

(IDF Curve, Runoff Coefficients, FEMA Firmette)

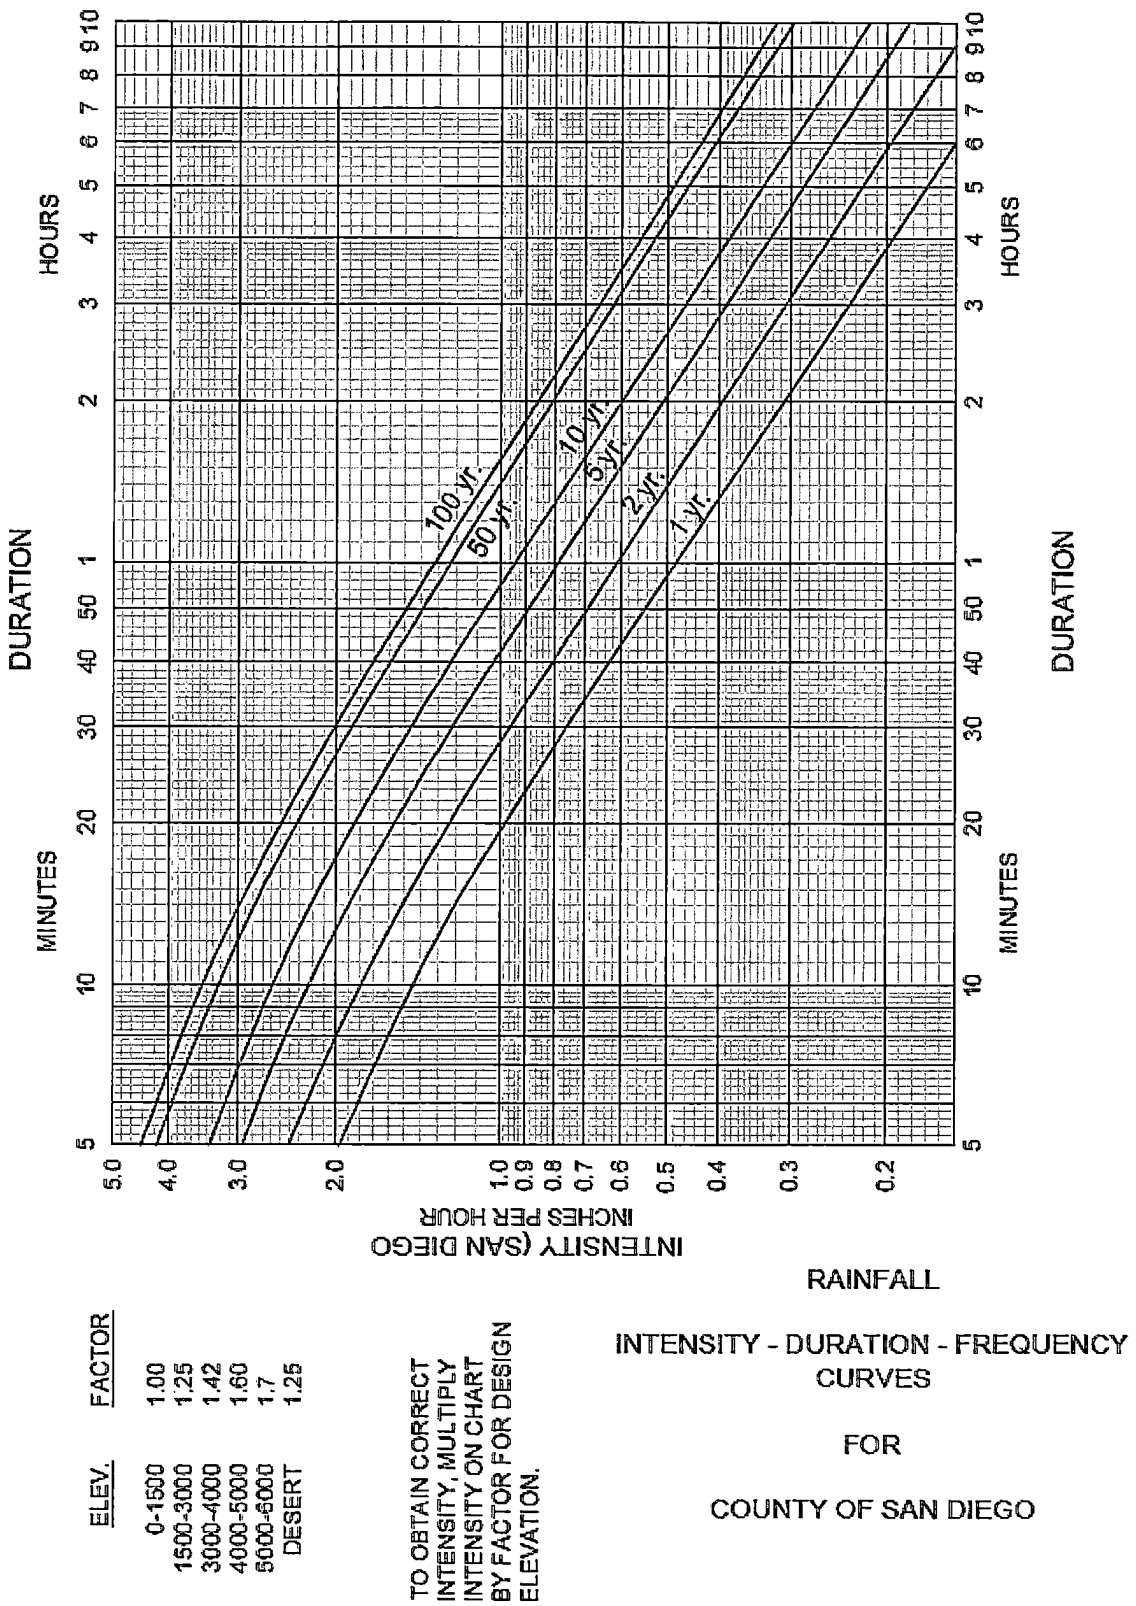

Figure A-1. Intensity-Duration-Frequency Design Chart

Table A-1. Runoff Coefficients for Rational Method

Land Use	Runoff Coefficient (C)
	Soil Type [1]
Residential:	
Single Family	0.55
Multi-Units	0.70
Mobile Homes	0.65
Rural (lots greater than ½ acre)	0.45
Commercial [2]	
80% Impervious	0.85
Industrial [2]	
90% Impervious	0.95

Note:
[1] Type D soil to be used for all areas.
[2] Where actual conditions deviate significantly from the tabulated imperviousness values of 80% or 90%, the values given for coefficient C, may be revised by multiplying 80% or 90% by the ratio of actual imperviousness to the tabulated imperviousness. However, in case shall the final coefficient be less than 0.50. For example: Consider commercial property on D soil.

Actual imperviousness = 50%
Tabulated imperviousness = 80%
Revised C = (50/80) x 0.85 = 0.53

The values in Table A–1 are typical for urban areas. However, if the basin contains rural or agricultural land use, parks, golf courses, or other types of nonurban land use that are expected to be permanent, the appropriate value should be selected based upon the soil and cover and approved by the City.

NOTES TO USERS

For information and questions about this Flood Insurance Rate Map (FIRM), available products associated with this FIRM, including historic versions, the current map date for each FIRM panel, how to order products, or the National Flood Insurance Program (NFIP) in general, please call the FEMA Map Information eXchange at 1-877-FEMA-MAP (1-877-336-2627) or visit the FEMA Flood Map Service Center website at http://msc.fema.gov. Available products may include previously issued Letters of Map Change, a Flood Insurance Study Report, and/or digital versions of this map. Many of these products can beordered or obtained directly from the website.

Communities annexing land on adjacent FIRM panels must obtain a current copy of the adjacent panel as well as the current FIRM Index. These may be ordered directly from the Flood Map Service Center at the number listed above.

For community and countywide map dates refer to the Flood Insurance Study Report for this jurisdiction.

To determine if flood insurance is available in this community, contact your insurance agent or call the National Flood Insurance Program at 1-800-638-6620.

Basemap information shown on this FIRM was provided in digital format by USDA, Farm Service Agency (FSA). This information was derived from NAIP, dated April 11, 2018.

This map was exported from FEMA's National Flood Hazard Layer (NFHL) on **3/6/2019 1:42:39 PM** and does not reflect changes or amendments subsequent to this date and time. The NFHL and effective information may change or become superseded by new data over time. For additional information, please see the Flood Hazard Mapping Updates Overview Fact Sheet at https://www.fema.gov/media-library/assets/documents/118418

This map complies with FEMA's standards for the use of digital flood maps if it is not void as described below. The basemap shown complies with FEMA's basemap accuracy standards

This map image is void if the one or more of the following map elements do not appear: basemap imagery, flood zone labels, legend, scale bar, map creation date, community identifiers, FIRM panel number, and FIRM effective date.

- Area with Flood Risk due to Levee *Zone D*

OTHER AREAS
- NO SCREEN Area of Minimal Flood Hazard *Zone X*
- Effective LOMRs
- Area of Undetermined Flood Hazard *Zone*

GENERAL STRUCTURES
- Channel, Culvert, or Storm Sewer
- Levee, Dike, or Floodwall

OTHER FEATURES
- 20.2 / 17.5 Cross Sections with 1% Annual Chance / Water Surface Elevation
- Coastal Transect
- 513 Base Flood Elevation Line (BFE)
- Limit of Study
- Jurisdiction Boundary
- Coastal Transect Baseline
- Profile Baseline
- Hydrographic Feature

MAP PANELS
- Digital Data Available
- No Digital Data Available
- Unmapped

N

The pin displayed on the map is an approximate point selected by the user and does not represe an authoritative property location.

This map complies with FEMA's standards for the use of digital flood maps if it is not void as described below. The basemap shown complies with FEMA's basemap accuracy standards

The flood hazard information is derived directly from the authoritative NFHL web services provided by FEMA. This map was exported on 8/6/2019 at 1:45:19 PM and does not reflect changes or amendments subsequent to this date and time. The NFHL and effective information may change or become superseded by new data over time.

This map image is void if the one or more of the following map elements do not appear: basemap imagery, flood zone labels, legend, scale bar, map creation date, community identifiers, FIRM panel number, and FIRM effective date. Map images for unmapped and unmodernized areas cannot be used for regulatory purposes.

Time of concentration =   11.82 min.
Rainfall intensity =     3.176(In/Hr)
```

```
Summary of stream data:

Stream   Flow rate      TC            Rainfall Intensity
 No.       (CFS)       (min)                (In/Hr)

1       16.963     12.55                  3.106
2        4.793     11.82                  3.176
Qmax(1) =
           1.000 *    1.000 *    16.963) +
           0.978 *    1.000 *     4.793) + =      21.651
Qmax(2) =
           1.000 *    0.941 *    16.963) +
           1.000 *    1.000 *     4.793) + =      20.758

Total of 2 streams to confluence:
Flow rates before confluence point:
      16.963       4.793
Maximum flow rates at confluence using above data:
      21.651      20.758
Area of streams before confluence:
      12.010       2.920
Results of confluence:
Total flow rate =     21.651(CFS)
Time of concentration =    12.555 min.
Effective stream area after confluence =     14.930(Ac.)
End of computations, total study area =          14.930 (Ac.)

Process from Point/Station     1606.000 to Point/Station     1603.000
**** CONFLUENCE OF MINOR STREAMS ****
-------------------------------------------------------------------------
Along Main Stream number: 1 in normal stream number 2
Stream flow area =      3.230(Ac.)
Runoff from this stream =      4.434(CFS)
Time of concentration =   13.53 min.
Rainfall intensity =     3.021(In/Hr)
```

```
Summary of stream data:

Stream   Flow rate      TC            Rainfall Intensity
 No.       (CFS)       (min)                 (In/Hr)

1        4.278     10.45                 3.321
2        4.434     13.53                 3.021
Qmax(1) =
           1.000 *    1.000 *     4.278) +
           1.000 *    0.772 *     4.434) + =       7.703
Qmax(2) =
           0.910 *    1.000 *     4.278) +
           1.000 *    1.000 *     4.434) + =       8.326

Total of 2 streams to confluence:
Flow rates before confluence point:
      4.278       4.434
Maximum flow rates at confluence using above data:
       7.703       8.326
Area of streams before confluence:
       2.520       3.230
Results of confluence:
Total flow rate =      8.326(CFS)
Time of concentration =    13.531 min.
Effective stream area after confluence =      5.750(Ac.)
End of computations, total study area =          5.750 (Ac.)

**** CONFLUENCE OF MINOR STREAMS ****
____________________________________________________________________
Along Main Stream number: 1 in normal stream number 2
Stream flow area =      2.860(Ac.)
Runoff from this stream =      4.808(CFS)
Time of concentration =    7.71 min.
Rainfall intensity =     3.709(In/Hr)
Summary of stream data:

Stream    Flow rate      TC            Rainfall Intensity
 No.        (CFS)      (min)                 (In/Hr)

1         3.300     32.82                  1.991
2         4.808      7.71                  3.709
Qmax(1) =
            1.000 *    1.000 *     3.300) +
            0.537 *    1.000 *     4.808) + =       5.881
Qmax(2) =
            1.000 *    0.235 *     3.300) +
            1.000 *    1.000 *     4.808) + =       5.583

Total of 2 streams to confluence:
Flow rates before confluence point:
        3.300        4.808
Maximum flow rates at confluence using above data:
        5.881        5.583
Area of streams before confluence:
        6.960        2.860
Results of confluence:
Total flow rate =      5.881(CFS)
Time of concentration =    32.823 min.
Effective stream area after confluence =      9.820(Ac.)
End of computations, total study area =           9.820 (Ac.)

           1.000 *    0.603 *     2.000) +
           0.650 *    1.000 *     8.566) +
           1.000 *    1.000 *     2.600) + =       9.377

Total of 3 streams to confluence:
Flow rates before confluence point:
       2.000       8.566       2.600
Maximum flow rates at confluence using above data:
       8.336       9.783       9.377
Area of streams before confluence:
       4.720       4.650       5.560
Results of confluence:
Total flow rate =      9.783(CFS)
Time of concentration =     5.974 min.
Effective stream area after confluence =     14.930(Ac.)
End of computations, total study area =          14.930 (Ac.)
```

Storm Event:

Pond Volume Equations
* Incremental volume computed by the Conic Method for Reservoir Volumes.

Volume = (1/3) * (EL2 - El1) * (Area1 + Area2 + sqr(Area1 * Area2))

where:	EL1, EL2	Lower and upper elevations of the increment
	Area1, Area2	Areas computed for EL1, EL2, respectively
	Volume	Incremental volume between EL1 and EL2
