SECTION 1

INTRODUCTION

This greenhouse gas technical study analyzes the proposed Old Town Community Plan Update (CPU). The Old Town CPU area is centrally located to the north of Downtown San Diego and south of Mission Bay. The Old Town Community Plan area lies between the Midway Pacific-Highway Community Plan area to the west and Mission Hills and Mission Valley to the east. The Old Town CPU provides a long-range guide for the future physical development of the community. The existing Old Town Community Plan was last updated in 1987. The proposed CPU, and associated actions, will ensure consistency of the CPU with and incorporate relevant policies from the City of San Diego General Plan (General Plan), as well as provide a long-range, comprehensive policy framework and vision for growth and development in the Old Town community through 2035.

The greenhouse gas (GHG) analysis was prepared to support the City of San Diego environmental review process. The purpose of this report is to discuss global climate change and existing GHG emissions sources and estimate the emissions from implementation of the proposed CPU.

GHG emissions have the potential to adversely affect the environment because such emissions contribute, on a cumulative basis, to global climate change. Global climate change also has the potential to result in sea level rise (resulting in flooding of low-lying areas), affect rainfall and snowfall (leading to changes in water supply and runoff), affect temperatures and habitats (affecting biological and agricultural resources), and result in many other adverse effects.

1.1 PROJECT DESCRIPTION

The project includes the comprehensive update to the Old Town Community Plan, which is intended to guide development through 2035 build-out of the Community Plan. The proposed CPU provides a detailed policy direction to implement the General Plan with respect to the distribution and arrangement of land uses (public and private); local street and transit network; prioritization and provision of public facilities, community, and site-specific urban design guidelines; and recommendations to preserve and enhance natural open space and historic and cultural resources within the Old Town community.

The guiding principles for the proposed CPU include the vision for Old Town community as an attractive, vibrant, and healthy community that respects the importance of Old Town San Diego as the site of initial settlement in the City and the birthplace of the State of California. The proposed CPU also envisions the community as a pedestrian-oriented historical small town and provide policy direction that new buildings and uses enhance the community character and livability with an emphasis on design that respects the history of the community and encourages pedestrian activity. The proposed CPU identifies the need for a community with a balance of residential and visitor-serving uses. The CPU identifies the community's mix of pedestrian-oriented residential, commercial, and public space served by the Old Town Transit Center is consistent with the "City of Villages" General Plan concept.

SECTION 2

EXISTING CONDITIONS

2.1 SCIENTIFIC BASIS OF CLIMATE CHANGE

Certain gases in the earth's atmosphere, classified as GHGs, play a critical role in determining the earth's surface temperature. A portion of the solar radiation that enters the earth's atmosphere is absorbed by the earth's surface, and a smaller portion of this radiation is reflected back toward space. This infrared radiation (i.e., thermal heat) is absorbed by GHGs within the earth's atmosphere. As a result, infrared radiation released from the earth that otherwise would have escaped back into space is instead "trapped," resulting in a warming of the atmosphere. This phenomenon, known as the "greenhouse effect," is responsible for maintaining a habitable climate on the earth.

GHGs are present in the atmosphere naturally, are released by natural and anthropogenic sources, and are formed from secondary reactions taking place in the atmosphere. Natural sources of GHGs include the respiration of humans, animals and plants, decomposition of organic matter, and evaporation from the oceans. Anthropogenic sources include the combustion of fossil fuels, waste treatment, and agricultural processes. The following are GHGs that are widely accepted as the principal contributors to human-induced global climate change:

- Carbon dioxide (CO₂)
- Methane (CH₄)
- Nitrous oxide (N₂O)
- Hydrofluorocarbons (HFCs)
- Perfluorocarbons (PFCs)
- Sulfur Hexafluoride (SF₆)
- Nitrogen Trifluoride (NF₃)

Emissions of CO₂ are byproducts of fossil fuel combustion. CH₄ is the main component of natural gas and is associated with agricultural practices and landfills. N₂O is a colorless GHG that results from industrial processes, vehicle emissions, and agricultural practices. HFCs are synthetic chemicals used as a substitute for chlorofluorocarbons in automobile air conditioners and refrigerants. PFCs are produced as a byproduct of various industrial processes associated with aluminum production and the manufacturing of semiconductors. SF₆ is an inorganic, odorless, colorless, nontoxic, nonflammable GHG used for insulation in electric power transmission and distribution equipment, and in semiconductor manufacturing. NF₃ is used in the electronics industry during the manufacturing of consumer items, including photovoltaic solar panels and liquid-crystal-display (i.e., LCD) television screens.

Global warming potential (GWP) is a concept developed to compare the ability of each GHG to trap heat in the atmosphere relative to CO₂. The GWP of a GHG is based on several factors, including the relative effectiveness of a gas to absorb infrared radiation and length of time (i.e., lifetime) that the gas remains in the atmosphere ("atmospheric lifetime"). The reference gas for GWP is CO₂; therefore, CO₂ has a GWP of 1. The other main GHGs that have been attributed to human activity include CH₄, which has a GWP of 25, and N₂O, which has a GWP of 298 (IPCC 2013). For example, 1 ton of CH₄ has the same contribution to the greenhouse effect as approximately 25 tons of CO₂. GHGs with lower emissions rates than CO₂

may still contribute to climate change, because they are more effective at absorbing outgoing infrared radiation than CO₂ (i.e., high GWP). The concept of CO₂-equivalents (CO₂e) is used to account for the different GWP potentials of GHGs to absorb infrared radiation.

Although the exact lifetime of any particular GHG molecule is dependent on multiple variables, it is understood by scientists who study atmospheric chemistry that more CO₂ is emitted into the atmosphere than is sequestered by ocean uptake, vegetation, and other forms of sequestration. GHG emissions related to human activities have been determined as “extremely likely” to be responsible (indicating 95 percent certainty) for intensifying the greenhouse effect and leading to a trend of unnatural warming of the earth’s atmosphere and oceans, with corresponding effects on global circulation patterns and climate (ARB 2014a). The quantity of GHGs that it takes to ultimately result in climate change is not precisely known; however, no single project is expected to measurably contribute to a noticeable incremental change in the global average temperature, or to a global, local, or micro climate.

2.2 GHG EMISSION SOURCES

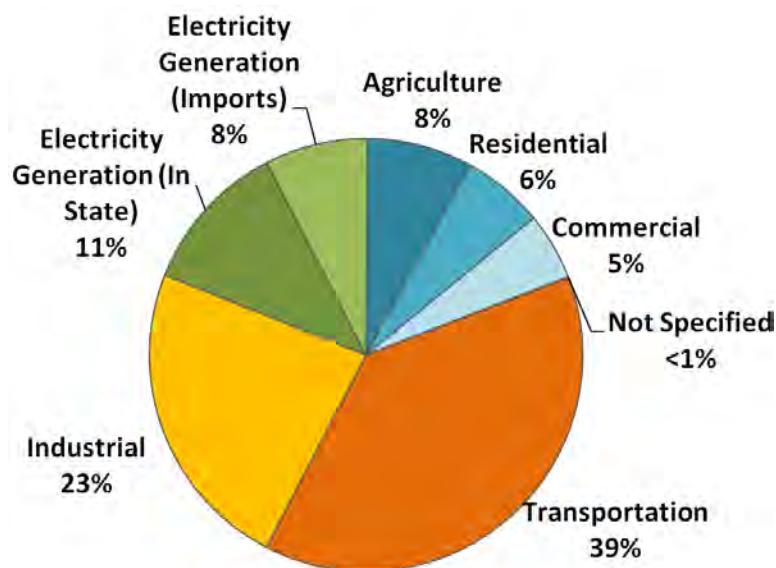

GHG emissions contributing to global climate change are attributable in large part to human activities associated with the transportation, industrial/manufacturing, electric utility, residential, commercial, and agricultural categories. Emissions of CO₂ are byproducts of fossil fuel combustion, and CH₄, a highly potent GHG, is the primary component in natural gas and is associated with agricultural practices and landfills. N₂O is also largely attributable to agricultural practices and soil management.

For purposes of accounting for and regulating GHG emissions, sources of GHG emissions are grouped into emission categories. The California Air Resources Board (ARB) identifies the following main GHG emission categories that account for most anthropogenic GHG emissions generated within California:

- *Transportation*: On-road motor vehicles, recreational vehicles, aviation, ships, and rail
- *Electric Power*: Use and production of electrical energy
- *Industrial*: Mainly stationary sources (e.g., boilers and engines) associated with process emissions
- *Commercial and Residential*: Area sources, such as landscape maintenance equipment, fireplaces, and consumption of natural gas for space and water heating
- *Agriculture*: Agricultural sources that include off-road farm equipment; irrigation pumps; crop residue burning (CO₂); and emissions from flooded soils, livestock waste, crop residue decomposition, and fertilizer volatilization (CH₄ and N₂O)
- *High GWP*: Refrigerants for stationary and mobile-source air conditioning and refrigeration, electrical insulation (e.g., SF₆), and various consumer products that use pressurized containers
- *Recycling and Waste*: Waste management facilities and landfills; primary emissions are CO₂ from combustion and CH₄ from landfills and wastewater treatment

California

ARB performs an annual GHG inventory for emissions and sinks of the six major GHGs. As shown in Figure 2, California produced 440 million metric tons (MMT) of CO₂e in 2015. Combustion of fossil fuel in the transportation category was the single largest source of California's GHG emissions in 2015, accounting for 39 percent of total GHG emissions in the state. The transportation category was followed by the industrial category, which accounts for 23 percent of total GHG emissions in California, the electric power generation category (including in-state and out-of-state sources), which accounts for 19 percent of total GHG emissions in California, and the agriculture sector which accounts for 8 percent of the state's total GHG emissions (ARB 2017).

Source: ARB 2017.

Figure 2. 2015 California GHG Emissions by Category

San Diego County

The University of San Diego School of Law, Energy Policy Initiative Center, prepared a GHG inventory for San Diego County in 2008. The inventory was updated in 2013 using the best available data and following the U.S. Community Protocol for Accounting and Reporting of GHG Emissions (University of San Diego 2013). Total GHG emissions in San Diego County in 2010 were estimated to be 32.1 MMT of CO₂e. This represents a 9 percent increase compared to 1990 emissions levels of 29 MMT CO₂e (University of San Diego 2013).

Transportation is the largest emissions sector, accounting for approximately 14 MMT of CO₂e, or 43 percent of total emissions. Energy consumption, including electricity and natural gas use, is the next largest source of emissions, at 33 percent of the total.

City of San Diego

The City of San Diego emitted approximately 15.5 million tons (MT) of GHGs in 1990 (City of San Diego 2005). Citywide emission levels were previously projected to result in an increase to 22.5 MT per year by 2010. The most recent GHG inventory for the year 2015 estimated the total emissions at 10.8 MMT CO₂e per year (City of San Diego 2016). Transportation is the largest emissions sector, accounting for approximately 54 percent of total emissions. Energy consumption is the next largest source of emissions, at 44 percent of the total. Accounting for future population and economic growth, the City estimates that GHG emissions will increase to approximately 14.1 MMT CO₂e in 2020 and 16.7 MMT CO₂e in 2035 (City of San Diego 2016).

2.3 GLOBAL CLIMATE TRENDS AND ASSOCIATED IMPACTS

Trends of Climate Change

The Intergovernmental Panel on Climate Change (IPCC) concluded that variations in natural phenomena, such as solar radiation and volcanoes, produced most of the warming of the earth from pre-industrial times to 1950. These variations in natural phenomena also had a small cooling effect. From 1950 to the present, increasing GHG concentrations resulting from human activity, such as fossil fuel burning and deforestation, have been responsible for most of the observed temperature increase.

Global surface temperature has increased by approximately 1.53 degrees Fahrenheit (°F) over the last 140 years (IPCC 2013); however, the rate of increase in global average surface temperature has not been consistent. The last three decades have warmed at a much faster rate per decade (IPCC 2013).

During the same period when increased global warming has occurred, many other changes have occurred in other natural systems. Sea levels have risen; precipitation patterns throughout the world have shifted, with some areas becoming wetter and others drier; snowlines have risen in elevation, resulting in changes to the snowpack, runoff, and water storage; and numerous other conditions have been observed. Although it is difficult to prove a definitive cause-and-effect relationship between global warming and other observed changes to natural systems, there is a high level of confidence in the scientific community that these changes are a direct result of increased global temperatures caused by the increased presence of GHGs in the atmosphere (IPCC 2013).

Additional changes related to climate change can be expected by the year 2050 and on to the end of the century, including the following:

- California's mean temperature may rise by 2.7°F by 2050 and by 4.1°F to 8.6°F by the end of the century (CEC 2012). Temperatures in San Diego County may rise by 3.2°F to 5.8°F during that same period (CEC 2016).
- A consistent rise in sea level has been recorded worldwide over the last 100 years. Rising average sea level over the past century has been attributed primarily to warming of the world's oceans, the related thermal expansion of ocean waters, and the addition of water to the world's oceans from the melting of land-based polar ice (IPCC 2007). Sea level rise is expected to continue, and the most recent climate science report, Sea Level Rise for the Coasts of California,

Oregon, and Washington: Past, Present, and Future, has estimated that sea levels along the U.S. Pacific coast will increase by up to 66 inches by 2100 (NRC 2012). The project site would not be subject to flooding as a result of climate-change-related sea level rise.

- Various California climate models provide mixed results regarding forecasted changes in total annual precipitation in the state through the end of this century. However, recent projections suggest that 30-year statewide average precipitation will decline by more than 10% (CEC 2012).
- Historically, extreme warm temperatures in the San Diego region have mostly occurred in July and August, but as climate warming continues, the occurrences of these events will likely begin in June and could continue to take place into September. All simulations indicate that hot daytime and nighttime temperatures (heat waves) will increase in frequency, magnitude, and duration (San Diego Foundation 2008).

SECTION 3 METHODOLOGY

GHG emissions due to the construction and operation of future projects under the proposed Old Town CPU were calculated using California Emissions Estimator Model (CalEEMod) version 2016.3.1. The emissions sources include construction (off-road vehicles), mobile (on road vehicles), area (fireplaces, consumer products [cleansers, aerosols, and solvents], landscape maintenance equipment, and architectural coatings), water and wastewater, and solid waste sources. As explained previously, GHG emissions are estimated in terms of CO₂e to account for the different GWP potentials of GHGs. Where project-specific data was not available, model inputs were based on default CalEEMod estimates as explained in more detail below.

Construction Emissions

At a program level, it would be speculative to estimate the schedule and construction requirements of individual projects that could occur in the Old Town CPU areas. In addition, GHG emissions would occur based on the entire construction activities through 2035. Thus, this analysis relies on the methodology used in the San Diego County Updated Greenhouse Gas Inventory (San Diego County 2013), which forecasts that between 2015 and 2035 construction emissions would comprise roughly 2.1 percent of total GHG emissions within the County of San Diego. Therefore, based on the operational GHG emissions estimated in Table 1, total construction emissions for the proposed Old Town CPU would be 609 MT CO₂e.

Operation Emissions

In order to analyze the GHG emissions associated with implementation of the proposed Old Town CPU and associated discretionary actions, an inventory was developed based on the land use designations associated with the adopted and proposed Community Plans. Considering that the adopted Community Plan projects have not yet been completed at the time of this analysis, an analysis of existing emissions compared with the proposed Old Town CPU improvements would not accurately disclose the impacts of the project. Rather, comparing GHG emissions from future operations with the adopted Community Plan and the proposed Old Town CPU provides the best indicator of the project's long-term effect on GHG emissions. Therefore, the analysis of the proposed Old Town CPU and associated discretionary actions is based on the net change in future GHG emissions estimates derived from the adopted Community Plan.

As compared to the existing land uses, the proposed Old Town CPU and associated discretionary actions would reduce institutional land uses while increasing the development of commercial uses and multi-family dwelling units. This change represents an increase in land use types and density in the Community Plan area. The proposed Old Town CPU and associated discretionary actions would change the planned land use mix as follows:

- Increase the projected number of multi-family residential units by approximately 26 percent;
- Decrease the projected number of single-family residential units by approximately 35 percent;
- Increase the amount of land designated for commercial development by 59 percent; and
- Decrease the amount of land designated for institutional development by 48 percent.

The following subsections describe the assumptions and methodology used for the mobile, energy, area, water and wastewater, and solid waste emission sources.

Mobile Source Emissions

GHG emissions from vehicles are calculated based on the vehicle type, the trip rate, and trip length for each land use. Mobile source emissions were estimated based on the vehicle miles traveled (VMT) for the area estimated in the TIS (Chen Ryan 2017). GHG emissions generated from mobile sources were estimated based on CARB's Emission Factor (EMFAC2014) model. EMFAC2014 includes GHG reducing effects from the implementation of Pavley I (Clean Car Standards) and the Low Carbon Fuel Standard, and are thus considered in the calculation of emissions.

The proposed Old Town CPU encourages increased development diversity by increasing commercial and multi-family land uses in certain areas, decreasing the number of planned institutional land uses. The proposed Old Town CPU and associated discretionary actions proposes an increase in multi-family residences in close proximity to transit and existing commercial uses.

Energy Source Emissions

CalEEMod estimates GHG emissions from energy use by multiplying average rates of residential and non-residential energy consumption by the number of residential units and non-residential square footage to obtain total projected energy use. This value is then multiplied by electricity and natural gas GHG emission factors applicable to the project location and utility provider.

Building energy use is typically divided into energy consumed by the built environment and energy consumed by uses that are independent of the construction of the building such as plug-in appliances. In California, Title 24 governs energy consumed by the built environment, mechanical systems, and some types of fixed lighting. Non-building energy use, or “plug-in energy use,” can be further subdivided by specific end-use (refrigeration, cooking, office equipment, etc.).

Energy consumption values are based on the California Energy Commission (CEC) sponsored *California Commercial End Use Survey and Residential Appliance Saturation Survey* studies, which identify energy use by building type and climate zone. CalEEMod 2016.3.1 is based on the 2013 Title 24 energy code (Part 6 of the Building Code).

The Old Town CPU area would be served by San Diego Gas & Electric (SDG&E). Therefore, SDG&E's specific energy intensity factors (i.e., the amount of CO₂, CH₄, and N₂O per kilowatt-hour) are used in the calculations of GHG emissions. The state mandate for renewable energy is 33 percent by 2020 and 50 percent by 2030 under the RPS. However, the analysis conservatively assumes the same RPS as existing conditions.

Area Source Emissions

Area sources include GHG emissions that would occur from the use of landscaping and related equipment. The use of landscape equipment emits GHGs associated with the equipment's fuel combustion.

Water and Wastewater Emissions

The amount of water used and wastewater generated by a project has indirect GHG emissions associated with it. These emissions are a result of the energy used to supply, distribute, and treat the water and wastewater. In addition to the indirect GHG emissions associated with energy use, wastewater treatment can directly emit both CH₄ and N₂O.

The indoor and outdoor water use consumption data in CalEEMod for each land use subtype comes from the Pacific Institute's Waste Not, Want Not: The Potential for Urban Water Conservation in California 2003 and the American Water Works Association Research Foundation's Commercial and Institutional End Uses of Water 2000. Based on those reports, a percentage of total water consumption was dedicated to landscape irrigation, which is used to determine outdoor water use. Wastewater generation was similarly based on a reported percentage of total indoor water use (ARB 2008).

In addition to water reductions under the California Green Building Standards Code, the GHG emissions from the energy used to transport the water are affected by RPS. As discussed previously, the analysis conservatively assumes existing RPS.

Solid Waste Emissions

The disposal of solid waste produces GHG emissions from anaerobic decomposition in landfills, incineration, and transportation of waste. To calculate the GHG emissions generated by disposing of solid waste for the project, CalEEMod uses waste disposal rates identified by California Department of Resources Recycling and Recovery to calculate the total volume of solid waste. The methods for quantifying GHG emissions from solid waste are based on the Intergovernmental Panel on Climate Change (IPCC) method using the degradable organic content of waste. GHG emissions associated with the project's waste disposal were calculated using these parameters. No solid waste reductions were modeled.

This page intentionally left blank.

SECTION 4 PROJECT IMPACTS

Based on the methodology summarized above, GHG emissions were calculated for the land uses of the adopted Community Plan (in 2035), and the land uses of the proposed Old Town CPU and associated discretionary actions (in 2035). Table 1 summarizes the GHG emissions under each scenario. Appendix A contains additional methodology and modeling details.

Table 1
GHG Emissions for the Old Town Community Plan Area
(MT CO₂e per Year)

| Emission Source | Existing | Adopted Community Plan | Proposed CPU | Difference (Proposed – Adopted) |
|----------------------|---------------|------------------------|---------------|---------------------------------|
| Mobile Sources | 25,025 | 17,300 | 17,654 | 355 |
| Energy Use | 9,182 | 10,533 | 9,802 | (731) |
| Area Sources | 724 | 388 | 435 | 46 |
| Solid Waste Disposal | 767 | 896 | 816 | (80) ¹ |
| Water Use | 1,823 | 1,985 | 1,798 | (186) |
| Construction | n/a | 653 | 641 | (13) |
| TOTAL | 37,521 | 31,755 | 31,145 | (609) |

Source: Estimated by AECOM in 2017.

Note: Totals may not add due to rounding.

¹ Solid waste disposal associated with GHG emissions decrease based on changes in land use from the adopted Community Plan to the proposed CPU. Waste generation rates vary for each land use; the largest decrease in solid waste is a result from the reduction in some existing industrial uses.

As shown in the Table 1, implementation of the proposed Old Town CPU and associated discretionary actions would result in a decrease in GHG emissions of 609 MT CO₂e per year when compared to the emissions that would occur under the adopted Community Plan.

1.3 User Entered Comments & Non-Default Data

Old Town 1987 CP Adopted Plan - San Diego County, Annual

Project Characteristics - Operational emissions at build-out 2035.

Land Use - Land uses associated with full build-out of adopted plan. Tourist attraction land use included in hotel land uses. Industrial land uses includes transit center and utilities.

Construction Phase - Operations only run.

Off-road Equipment - Operations only run.

Off-road Equipment - Operations only run.

Off-road Equipment - Operations only run.

Trips and VMT - Operations only run.

Grading - Operations only run.

Architectural Coating - Operations only run.

Vehicle Trips - Mobile source emissions calculated separately.

Vehicle Emission Factors -

Vehicle Emission Factors -

Woodstoves - Assumes no woodstoves or wood fireplaces.

Energy Use -

Water And Wastewater -

Solid Waste -

1.3 User Entered Comments & Non-Default Data

Old Town Existing - San Diego County, Annual

Project Characteristics - Existing conditions - operations only run.

Land Use - Industrial land use includes utilities, military, and transit center. Institutional land use excludes former Caltrans building. Hotel land use includes tourist attraction square footage. Other asphalt surfaces land use includes transportation and parking. City park land use includes undeveloped, vacant land, and open space acreage.

Construction Phase - Operations only.

Off-road Equipment - Operations only.

Off-road Equipment - Operations only.

Grading - Operations only.

Trips and VMT - Operations only.

Architectural Coating - Operations only.

Vehicle Trips - Operational mobile emissions calculated separately.

Area Coating - SDAPCD Rule 67

Consumer Products - EFs consistent with adopted plan and CPU run.

Energy Use -
